# Project Euler #27: Quadratic primes

### **Problem Statement**

This problem is a programming version of Problem 27 from projecteuler.net

Euler published the remarkable quadratic formula:

$$n^2 + n + 41$$

It turns out that the formula will produce 40 primes for the consecutive values n=0 to 39. However, when n=40,  $40^2+40+41=40(40+1)+41$  is divisible by 41, and certainly when n=41,  $41^2+41+41$  is clearly divisible by 41.

Using computers, the incredible formula  $n^2-79n+1601$  was discovered, which produces 80 primes for the consecutive values n=0 to 79. The product of the coefficients, -79 and 1601, is -126479.

Considering quadratics of the form:

$$n^2 + an + b$$
, where  $|a| \le N$  and  $|b| \le N$ 

where |n| is the modulus/absolute value of n e.g. |11|=11 and |-4|=4

Find the coefficients, a and b, for the quadratic expression that produces the maximum number of primes for consecutive values of n, starting with n=0.

**Note** For this challenge you can assume solution to be unique.

### **Input Format**

The first line contains an integer N.

# **Output Format**

Print the value of a and b separated by space.

## **Constraints**

42 < N < 2000

# **Sample Input**

42

# **Sample Output**

-1 41

## **Explanation**

for a=-1 and b=41, you get 42 primes.
